# Outside of the box in particle collisions?

but: hadronization remnants ???

our focus: signal

# Building upon existing types of flavor tagging

## #1: jet flavor tagging

## #2: b quark charge tagging

# New #3: b hadron species tagging

$B_x$  identification for “hopeless”  $B_x$  decays

FCC-ee, one hemisphere, non-signal tracks only

- infer the type of quark with which b hadronized
  - use only non-signal tracks
- response is independent of the B hadron decay mode
  - can be calibrated in data with fully reconstructed decay modes
- from better to worse:
  - $B_c$ ,  $\Lambda_b$ ,  $B_s$ , ( $B^+$ ,  $B^0$ )
- performance at LHCb is expected to be similar or worse

# Use cases

- suppress background for non-peaking final states:
  - $B_c \rightarrow \ell \nu(\gamma)$ ,  $B_s \rightarrow \phi \nu \nu$
- design inclusive measurements:
  - $b \rightarrow s \ell \ell$  (?)
- hadronization fraction measurement w/o external inputs
- ....?

## $B_c$ hadronization at the FCC

The most developed use-case as of now,  
by **Xunwu Zuo** and **Vasilisa Guliaeva**

Presented at the Flavours at FCC Workshop by Xunwu:  
["Hadron species tagger at FCC-ee"](#)

# Motivated by Patrick's talk at the 1<sup>st</sup> FCC flavor workshop

## $B_c$ fragmentation fractions

- Most of the time,  $B_c$  production is measured with respect to  $B^+$

$$\mathcal{R}_{c/u} = \frac{\sigma(B_c^+) \times \mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)}{\sigma(B^+) \times \mathcal{B}(B^+ \rightarrow J/\psi K^+)}$$

$$R_{c/u} = (0.683 \pm 0.018 \pm 0.009)\%$$

[LHCb, PRL 114 (2015) 132001]

- $\sigma(B^+)$  (or  $f(B^+)$ ) is known with good precision at LHC or Z,  $\mathcal{B}(B^+ \rightarrow J/\psi K^+)$  also (2% precision [PDG])
- But there is no measurement of  $\sigma(B_c^+)$  (or  $f(B_c^+)$ ) nor  $\mathcal{B}(B_c^+ \rightarrow J/\psi \pi^+)$ , and theoretical computations vary by a factor  $\sim 10$ .
  - So a precise measurement of  $f(B_c)$  is not possible
  - Equivalently no absolute measurement of a branching fraction for  $B_c^+$  is available

8

# But: LHCb measurement with $B_c \rightarrow J/\psi \mu \nu$

Thanks to Marcello!

$$f_c = \begin{cases} (2.58 \pm 0.05 \pm 0.62 \pm 0.09) \cdot 10^{-3} & (7 \text{ TeV}) \\ (2.61 \pm 0.03 \pm 0.62 \pm 0.06) \cdot 10^{-3} & (13 \text{ TeV}) \end{cases},$$

# Training setup at the FCC

$Z \rightarrow qq$  events always 2 back-to-back jets

If one side is tagged a b-jet

## Truth assigned per hemisphere

- exactly 1 (truth level) b-hadron
- consider 5 labels  $B^0, B^\pm, B_s^0, B_s^\pm, \Lambda_b$ , i.e. Bd, Bu, Bs, Bc, Lb
- $Z \rightarrow bbbb$  not considered

Remark:

- $B_s^* \rightarrow B_s \gamma$  is labeled Bs
- $B_{s2}^* \rightarrow B^+ K^-$  is labeled Bu
- $B_c^* \rightarrow B_s \pi$  is labeled Bc

# Input information

**Standard Particle Transformer architecture**  
**use all available reconstructed info as input**

## **reconstructed particles**

- 4-vec, charge, true mass,
- angles relative to thrust axis
- full track parameters
- PID ( $dN/dx$ , mass from TOF)

## **reconstructed vertices (PV+SV)**

- 4-vec momentum
- 3-vec position
- number of tracks
- Chi2, significance of displacement
- angle relative to thrust axis

# Several types of the tagger

Consider 6 setups to understand performance

- **One hemisphere:** input info from a chosen hemisphere
- **Full event:** choose 1 hemisphere for tagging, but also include info from other hemisphere

- **All reco particles:** complete reconstructed info (including signal decay)
- **Excluding signal:** based on truth, mask all particles and vertices from signal decay chain, use everything else
- **Excluding signal excluding neutral:** based on truth, use only non-signal tracks

# All-inclusive (+signal) tagger performance: Bd

Setup: hemisphere  $\otimes$  all particles

# All-inclusive (+signal) tagger performance: Bc

Setup: hemisphere  $\otimes$  all particles

## Partial summary (1/3)

- All b-hadrons can be well-separated from others
- Worst case is  $B_s$  vs  $B_d$  ( $10^{-2}$  bkg rejection for 50% signal eff)
- Great performance for  $B_c$  and  $\Lambda_b$  (better than  $10^{-4}$  bkg rejection for 50% signal eff)

# Include vs Veto signal: Bc tag

hemisphere  $\otimes$

complete info

vs veto signal

vs veto signal & veto neutral

**significant reduction of  
separation power**

**But in case of Bc vs others, a  
good separation still retained**

# Include vs Veto signal: Bd tag

hemisphere ⊗

complete info

vs veto signal

vs veto signal & veto neutral

**significant reduction of  
separation power**

**In case of Bd vs others, tagging  
info almost purely come from  
signal itself**

## Partial summary (2/3)

- All b-hadrons can be well-separated from others
- Worst case is Bs vs Bd ( $10^{-2}$  bkg rejection for 50% signal eff)
- Great performance for Bc and  $\Lambda_b$  (better than  $10^{-4}$  bkg rejection for 50% signal eff)
- Tagging power comes from both signal decay itself and hadronization. Hadronization info is more useful in case of Bc than Bd

Why compare all these setups?

# Let's take a step back...

and think about why we wanted a tagger in the first place

# What kind of tagger?

We wanted to have an **inclusive tagger** to break circular logic

$$N_{B_c}^{obs} = \sum N_b f_{B_c} \epsilon_i^{tag} \mathcal{B}(B_c \rightarrow X_i) \epsilon_i^{reco} \xrightarrow[\text{independent of decay}]{\text{uniform } \epsilon_i} N_{B_c}^{obs} = N_b f_{B_c} \epsilon^{tag} \epsilon^{reco} \boxed{\sum \mathcal{B}(B_c \rightarrow X_i)} = 1$$

**Decay-aware tagger**

**Decay-agnostic tagger**

Exclude signal decay from tagger training  
uniform  $\epsilon$  by construction

But..... another circular logic:

without knowing the signal, which particles  
to exclude?

# What kind of tagger?

We wanted to have an **inclusive tagger** to break circular logic

$$N_{B_c}^{obs} = \sum N_b f_{B_c} \epsilon_i^{tag} \mathcal{B}(B_c \rightarrow X_i) \epsilon_i^{reco} \xrightarrow[\text{independent of decay}]{\text{uniform } \epsilon_i} N_{B_c}^{obs} = N_b f_{B_c} \epsilon^{tag} \epsilon^{reco} \boxed{\sum \mathcal{B}(B_c \rightarrow X_i)} = 1$$

## Decay-aware tagger

tagger uses decay info

Straightforward application

$\epsilon$  decay-dependent

Need to address 2 questions:

- To what extent is it decay-dependent?
- How to calibrate tagging eff?

## Decay-agnostic tagger

Exclude signal decay from tagger training

uniform  $\epsilon$  by construction

easy to calibrate, with candle modes

But..... another circular logic:

without knowing the signal, which particles to exclude?

- To what extent is it decay-dependent?
- How to calibrate tagging eff?

# A solution to break the loop

# uncertainty estimate

$$\epsilon^{tot} = \sum \mathcal{B}(B_c \rightarrow X_i) \epsilon_i^{tag}$$

$\delta\epsilon^{tot}$        $\delta\mathcal{B}_i$        $\delta\epsilon_i^{MC} + \delta\epsilon_i^{calib}$

theo unc, can  
be conservative

MC stats unc,  
approaches 0  
with big enough  
sample

per-object unc,  
can be calibrated  
in other ways with  
high precision

Vary all uncertainties randomly, take the envelope of variation  
as a (conservative) total uncertainty band.

# Explicit Bc decays

- A zoology of decay modes
- 12776 explicit decay modes found in sample
- 75% are  $B_c \rightarrow B_s$
- Only a small fraction are fully reconstructable

## 4 level of categories

1. Direct daughters of Bc (  $\rightarrow B_s, B_d, B_u, DD, J/\psi$  )
2. Sub modes (daughter decay type, hadronic, semilep)
3. Vertex topology (whether each vertex is reconstructable)
4. Individual decay chain

# Uncertainty estimate for a simple scenario

- Each BR is allowed to vary independently by +100%/-50%, keeping total = 1
- Ensemble of toys to make envelope
- The min/max line is the one toy where all 14,197 chains fluctuate to their extreme in the same direction at once
- since the chains are independent (per-chain the whole basis of the scheme), the probability of this joint configuration is  $\sim(\text{tail})^{14000} \approx 0$

# Estimate of the total uncertainty in $f_{B_c}$

- apply the same envelope estimate to other b-hadrons (likely conservative)
- consider other hadronization fractions are known up to 10% (1%) for syst scenarios
- **a precision in  $f_{B_c}$  at percent level seems very achievable**

# Informed BF variations for Bc decay chains

## BF variation scheme · knobs × scenarios

Bc factorises  $B_c \rightarrow X + Y$  then  $X \rightarrow U V$  · columns = the level each knob takes in that scenario

| KNOB                                                                                 | APPLIES TO                                                   | MEASURED (what-if) |      | SCENARIO (theory) |       |       |

per-chain, 20k toys,  $f_{\text{bkg}} = 10\%$ ; cell =  $\sigma_{\text{tot}}/S$  [%] at the optimal WP; labels =  $\pm$  variation in %. **Bold**: tight/mid/loose scenarios. \* what-if: hadronic Bc BF<sub>s</sub> measured. <sup>32</sup>

Worst offenders

## Summary (3/3)

- All b-hadrons can be well-separated from others
- Worst case is Bs vs Bd ( $10^{-2}$  bkg rejection for 50% signal eff)
- Great performance for Bc and  $\Lambda_b$  (better than  $10^{-4}$  bkg rejection for 50% signal eff)
- Tagging power comes from both signal decay itself and hadronization. Hadronization info is more useful in case of Bc than Bd
- A totally **inclusive, theory-independent**  $f_{Bc}$  measurement better than 2%

# Next (ongoing) steps

- Application/development of other use-cases
- Training and application to LEP data
- Training on LHCb MC and testing on LHCb data!
