## DARK Mo ${ }_{0} \mathrm{AGIX}_{\mathrm{o}}$

Dark photon searches at MAGIX

## U(1) Gauge boson

- Carrier of an unknown interaction between unknown particles
- Massive (mass unknown)
- No direct coupling with any SM field

## Kinetic mixing

- Same quantum numbers of the SM photon
- Transitions mediated by loops at unknown scales
- Assuming a particle of any mass charged under both fields.
- Mixing degree parameterized by $\varepsilon^{2}=\frac{\alpha^{\prime}}{\alpha}$
- $\alpha^{\prime}$ is the effective SM coupling

## Replace the SM photon in allowed processes

- Bremsstrahlung
- Schwinger term in muon magnetic moment
- Electron pair production

## Observable differences

- Kinematic differences due to the particle mass
- Cross section difference due to the additional diagrams

## Visible decays

- Relevant branching ratio of $\gamma^{\prime} \rightarrow S M$
- Possible if the dark photon is the LDP
- Fixed decay product invariant mass

## Invisible decays

- The dark photon decays in the dark sector
- Likely if the dark photon is not the LDP
- Reasonable to assume a complex dark sector (it should represents up to $85 \%$ of the universal mass)

## Bump hunting

- The DP decay products have a welldefined invariant mass
- Competing background are the similar SM photon processes
- Needs to locate a narrow "bump" on the continuous spectrum

## Fast ongoing developments

- Many new running experiments quickly filling the holes
- Will we still be competitive in $4 / 5$ years?

## Missing mass

- Measure all the final products
- Measure the missing invariant mass
- It's challenging to tag the proton

## Almost virgin territory

- Almost no constraint by current experiments
- Several competing experiments in development
- Important contributions to be made

## MAGIX DP <br> SIMULATION

## First benchmark of the MXWare software

- Extensible and configurable system
- More on Friday

## Event generator

- Custom beam, target and detector representation
- Pseudo- or quasi-random generator
- Complete event generation for further analysis
- Fast direct histogram generation

## Fast detector simulation

- The detector are represented by their phase space acceptance
- Detection efficiency parameterized in the acceptance

## Bachelor thesis of F. Berressem

## Full phase space generator

- Customizable phase space constraints
- Electron and proton angles and momenta
- Dark photon mass
- Restrictions to reduce run time

## Experimental parameters

- 105 MeV electron beam
- 10 days run time
- Luminosity $1.98710^{34} \mathrm{~cm}^{-2} \mathrm{~s}^{-1}$

## SETUP OPTIMIZATION

CONCLUSIONS

| Implement <br> background <br> process simulation | Bethe-Heitler |
| :--- | :--- |
| Implement the <br> visible decad <br> generator | And the bump hunting algorithm |
| Improved <br> detector <br> representation | Another possible student project |
| Adaptive Monte <br> Carlo generator | To reduce the run time and simulation errors |
|  | One of the general improvements of the simulation package |
| Putting all <br> together | Compute the MAGIX sensitivities for both processes complete detector simulation package |
